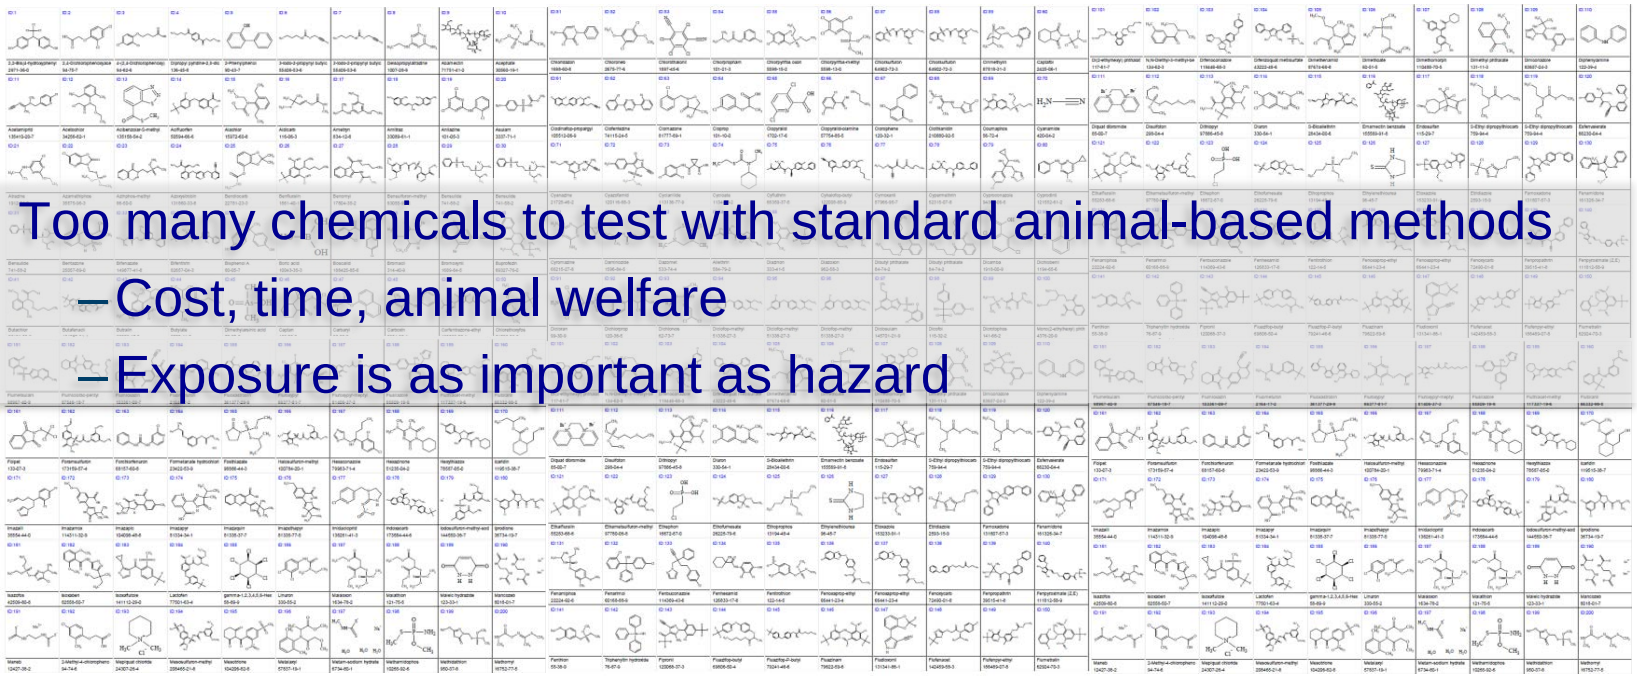
"*anything that we can do with a computer in toxicology*"



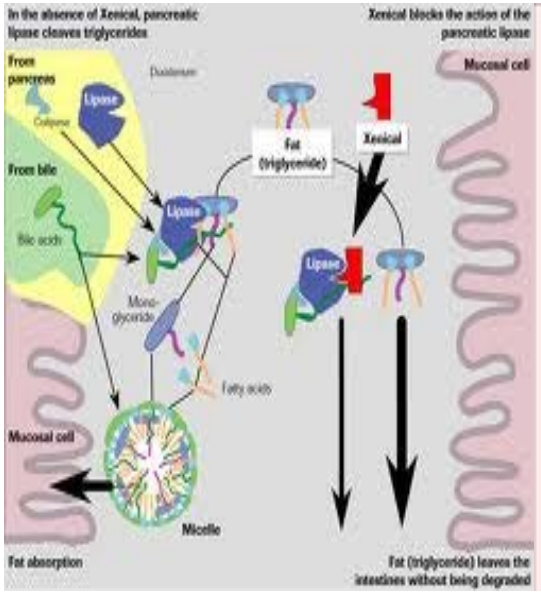
- Too many chemicals to test with standard animal-based methods
  - Cost, time, animal welfare
  - Exposure is as important as hazard

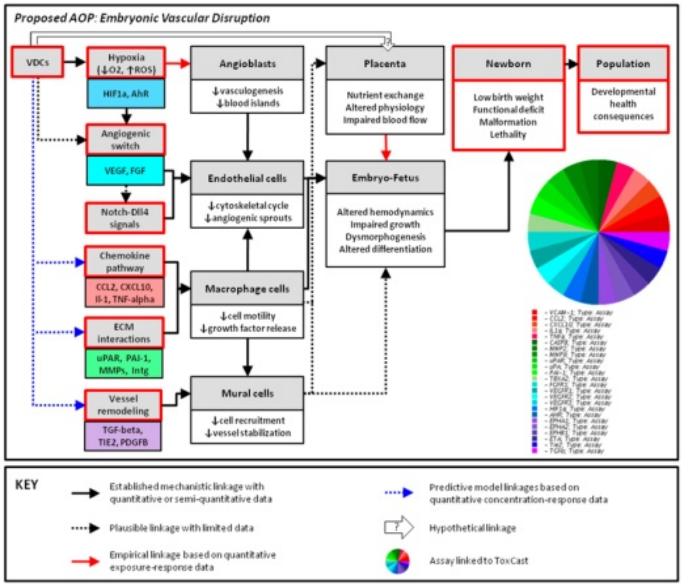
"*integration of modern computing and information technology with molecular biology to improve agency prioritization of data requirements and risk assessment of chemicals*"

Risk assessment of chemicals

Need for better mechanistic data

- Determine human relevance
- What is the relevant Mode of Action (MOA) or Adverse Outcome Pathway (AOP)?

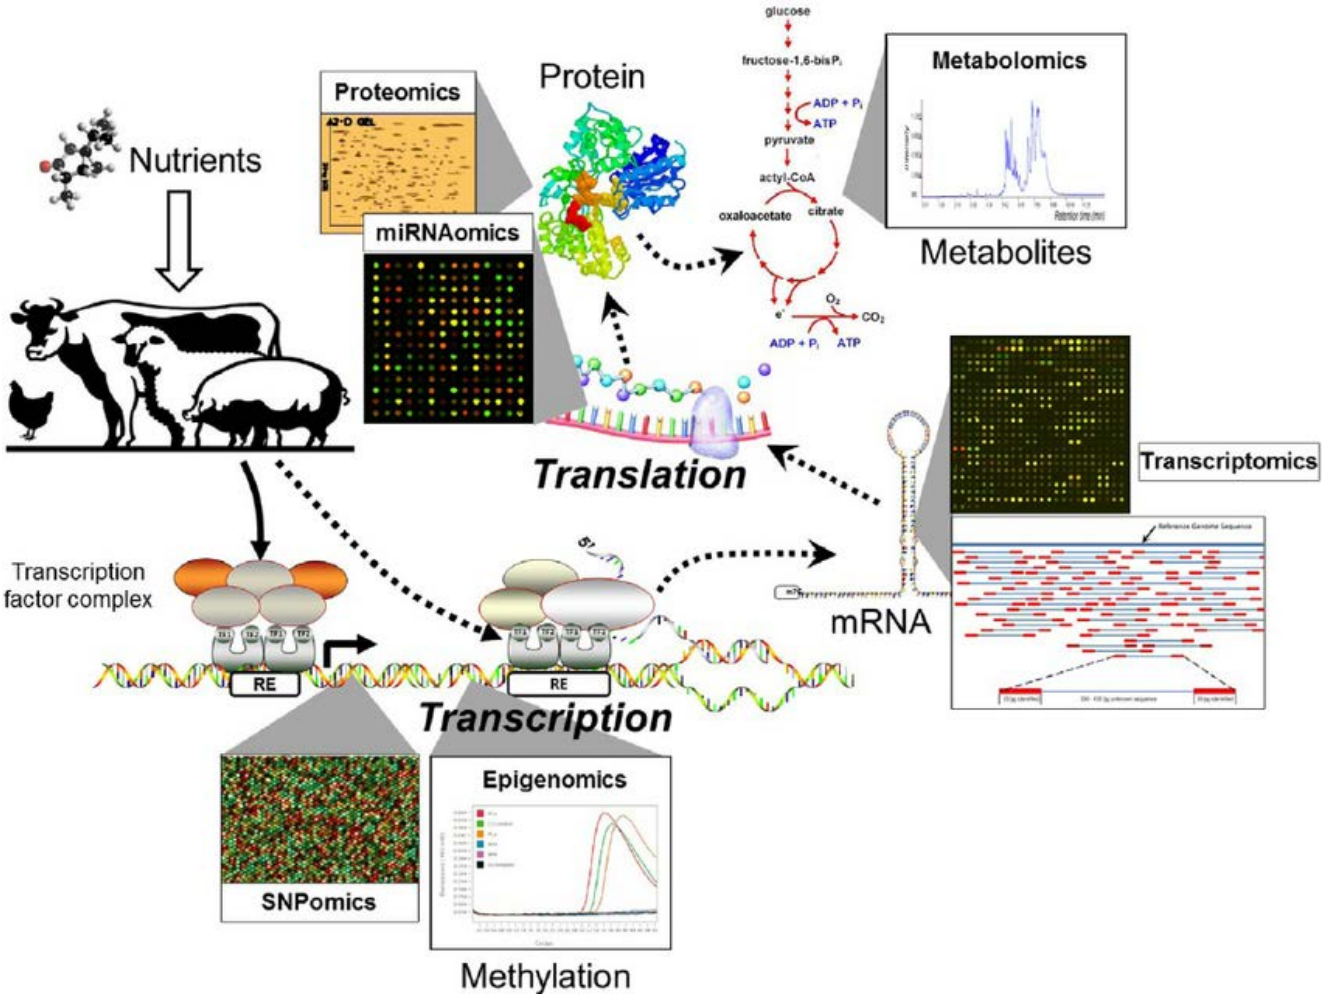




Bioinformatics for multi-omics

- Introduction to “omics”

- Metabolomics
- Metabonomics
- Transcriptomics
- Genomics
- Proteomics
- Bionomics
- Toxicogenomics
- And many more



But what is “omics”?

- A useful concept in biology which informally annotates a field of study ending in ‘-omics’. Omics aims at the collective characterization and quantification of pools of biological molecules that translate into the structure, dynamics and function, of an organism

- "Omics is a general term for a broad discipline of science and engineering for analyzing the interactions of biological information objects in various ‘omes’. […] The main focus is on: 1) mapping information objects such as genes, proteins, and ligands; 2) finding interaction relationships among the objects; 3) engineering the networks and objects to understand and manipulate the regulatory mechanisms; and 4) integrating various omes and omics subfields."

Development of generic multi-route lifetime PBPK model

H2020-MSCA-ITN-2017 GA - 766251

PBPK models serve three main purposes:

- internal dose assessment (I)

- to provide the framework for exposure reconstruction (III)

- to derive Biomonitoring Equivalents (BEs) for risk characterization (III)

PBPK models are modeling tools that describe the mechanisms of absorption, distribution, metabolism and elimination (ADME) of chemicals in the body resulting from acute and/or chronic exposure regimes. Within the boundary of the identified compartment (e.g., an organ or tissue or a group of organs or tissues), whatever inflows must be accounted for via whatever outflows or whatever is transformed into something else.

This mass balance is expressed as a mathematical equation with appropriate parameters carrying biological significance. A generic equation, for any tissue or organ, is:

$$V_i \frac{dC_{ij}}{dt} = Q_i (CA_j - CV_{ij}) - Metab_{ij} - E\lim_{ij} + Absorp_{ij} - \Pr Binding_{ij}$$

Development of generic multi-route lifetime PBPK model

H2020-MSCA-ITN-2017 GA - 766251

$$V_i \frac{dC_{ij}}{dt} = Q_i(CA_j - CV_{ij}) - Metab_{ij} - E\lim_{ij} + Absorp_{ij} - \Pr Binding_{ij}$$

Where:

V_i represents the volume of tissue group ***i***,

Q_i is the blood flow rate to tissue group ***i***,

CA_j is the concentration of chemical ***j*** in arterial blood, and

C_{ij} and CV_{ij} are the concentrations of chemical ***j*** in tissue group ***i*** and in the effluent venous blood from tissue ***i***, respectively.

$Metab_{ij}$ is the rate of metabolism for chemical ***j*** in tissue group ***i***; liver, being the principal organ for metabolism would have significant metabolism and, with some exception, usually $Metab_{ij}$ is equal to zero in other tissue groups.

$Elim_{ij}$ represents the rate of elimination from tissue group ***i*** (e.g., biliary excretion from the liver),

$Absorp_{ij}$ represents uptake of the chemical from dosing (e.g., oral dosing)

$PrBinding_{ij}$ represents protein binding of the chemical in the tissue. All these terms are zero unless there is definitive knowledge that the particular organ and tissue of interest has such processes.

Development of generic multi-route lifetime PBPK model

Development of generic multi-route lifetime PBPK model

NEUROSOME

H2020-MSCA-ITN-2017 GA - 766251

NEUROSOME: First training event

Heraklion, Crete, May 2019

Organ volumes (***V***) and blood flows (***Q***) were taken from the ICRP (2002) report and the obtained data were fitted to time (***T***) in order to exclude continuous time dependent non-lineal polynomial formulas in the form of:

$$V = a \cdot T^b + c \cdot T^d + e$$

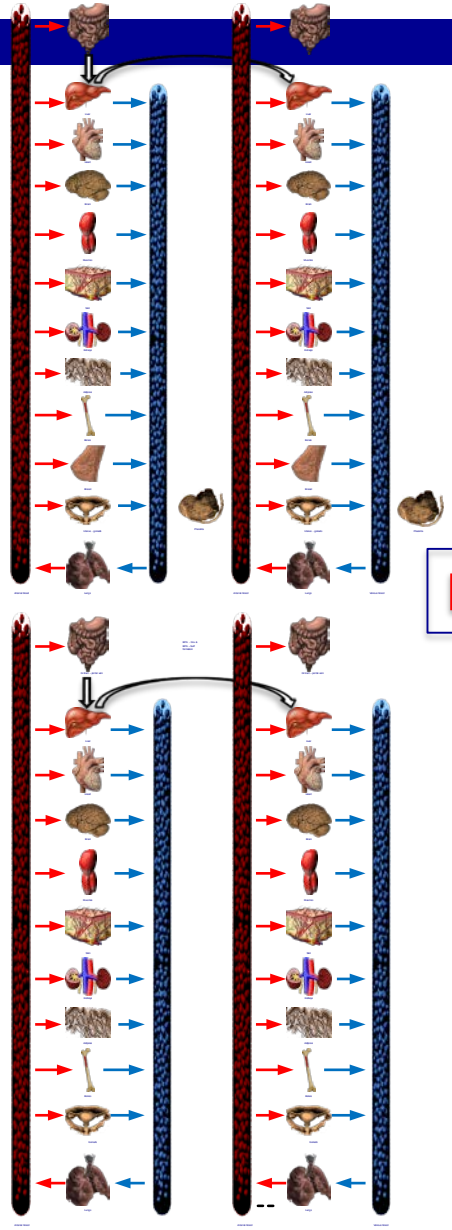
The permeability parameters PS were scaled according to the formula:

$$PS_{tissue\_child} = PS_{tissue\_adult} \left(\frac{V_{tissue\_child}}{V_{tissue\_adult}} \right)^{0.75}$$

Age dependent clearance:

$$CL_{INT} = \alpha_{ontogeny} \cdot CL_H \frac{Q_H}{Q_H - CL_H} \cdot \frac{1}{f_u}$$

where Q_H is the hepatic blood flow, CL_H is the plasma clearance, CL_{INT} is the intrinsic hepatic clearance per gram of liver weight and f_u is the fraction unbound in plasma, $\alpha_{ontogeny}$ is an ontogeny factor that represents the activity of the specific enzyme in relation to the age



Breast feeding link

$$V \frac{dC_{\_breast}}{dt} = PS_{\_cell\_breast} \cdot fu \cdot \left(C_{\_int\_breast} - \frac{C_{\_breast}}{K_{\_breast}} \right) - L_{excr}$$

$$L_{excr} = Q_{\_milk} \cdot \frac{C_{\_breast}}{K_{\_breast}} \cdot P_{\_milk/blood}$$

$$P_{\_milk/blood} = \frac{K_{ow} \cdot Fl_{\_tissue} + Fw_{\_tissue}}{K_{ow} \cdot Fl_{\_blood} + Fw_{\_blood}}$$

Mother – Fetus interaction

$$\frac{\partial Q_{uterus\_M}}{\partial t} = F_{uterus\_M} \times \left(C_{art\_M} - \frac{C_{uterus\_M}}{P_{uterus}} \right) - K_{d\_uter\_pla} \times \left(C_{placenta} - C_{uterus\_M} \right)$$

$$\frac{\partial Q_{placenta}}{\partial t} = K_{d\_uter\_pla} \times \left(C_{placenta} - C_{uterus\_M} \right) + F_{placenta\_B} \times \left(C_{art\_B} - \frac{C_{placenta}}{P_{placenta}} \right)$$

$$- K_{d\_pla\_amniot} \times \left(C_{placenta} - C_{amniot} \frac{P_{placenta}}{P_{amniot}} \right) - K_{m\_placenta} \times C_{placenta}$$

$$\frac{\partial Q_{amniot}}{\partial t} = K_{d\_pla\_amniot} \times \left(C_{placenta} - C_{amniot} \frac{P_{placenta}}{P_{amniot}} \right) + K_{e\_gut\_B} \times C_{gut\_B}$$

Statistical Analysis

1. Linear Free – Energy Relationship (LFER)

$$logSP = c + e \cdot E + s \cdot S + a \cdot A + b \cdot B + v \cdot V$$

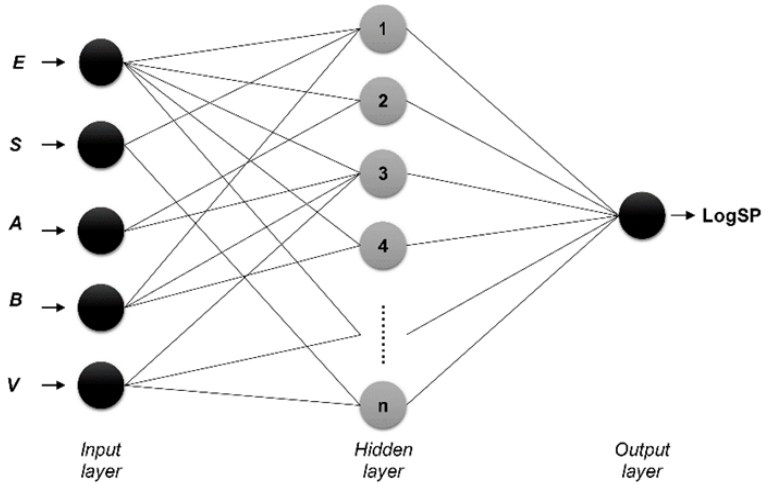
SP: biological property of a chemical (tissue/blood partition coefficients and parameters of metabolism)
E: excess molar refractivity of the chemical
S: chemical's dipolarity/polarizability
A: solute effective or summation hydrogen-bond acidity of the chemical
B: solute effective or summation hydrogen-bond basicity of the chemical
V: McGowan characteristic volume of the chemical
c, e, s, a, b, v: constants that reflect the properties of the chemical

2. Data collection

- Experimental values of $P_{tissue/blood}$ of 33 organic chemicals
- Experimental values of V_{maxc} and K_m of 29 organic chemicals
- Experimental and computed values of molecular descriptors (E, S, A, B, V)

3. Statistical Analysis

- a. Artificial Neural Networks (ANN)
  - Multi-Layer Perceptron (MLP) model using the scaled conjugate gradient back-propagation algorithm.
  - Input data divided into the training (70%), the validation (15%) and the testing (15%) data.



ANN example

- b. Non Linear Regression (NLR)
  - Form of the NLR model:
  - $$y = f(X, \beta) + \varepsilon$$

β: constants of LFER (c, e, s, a, b, v)

ε: error term

- Least Squares (LS) coupled with the Levenberg-Marquardt algorithm.

4. Expanding the Domain of Applicability

The QSAR model, derived from ANN analysis, was used:

- for the estimation of tissue/ blood partition coefficients for the main human tissues
- for several chemical compounds, categorized into chemical families, including hydrocarbons, aromatic and halogenated hydrocarbons, alcohols, ketones, ethers and esters.

The results were validated using the equation:

$$P_{tissue/blood} = \frac{P_{ow} \cdot Fl_{tissue} + P_{ow} \cdot Fw_{tissue}}{P_{ow} \cdot Fl_{blood} + P_{ow} \cdot Fw_{blood}}$$

P_{ow}: octanol/ water partition coefficient,

Fl_{tissue} and Fw_{tissue}: fractional contents of lipids and water in tissue, respectively, and

Fl_{blood} and Fw_{blood}: fractional contents of lipids and water in blood, respectively [4].

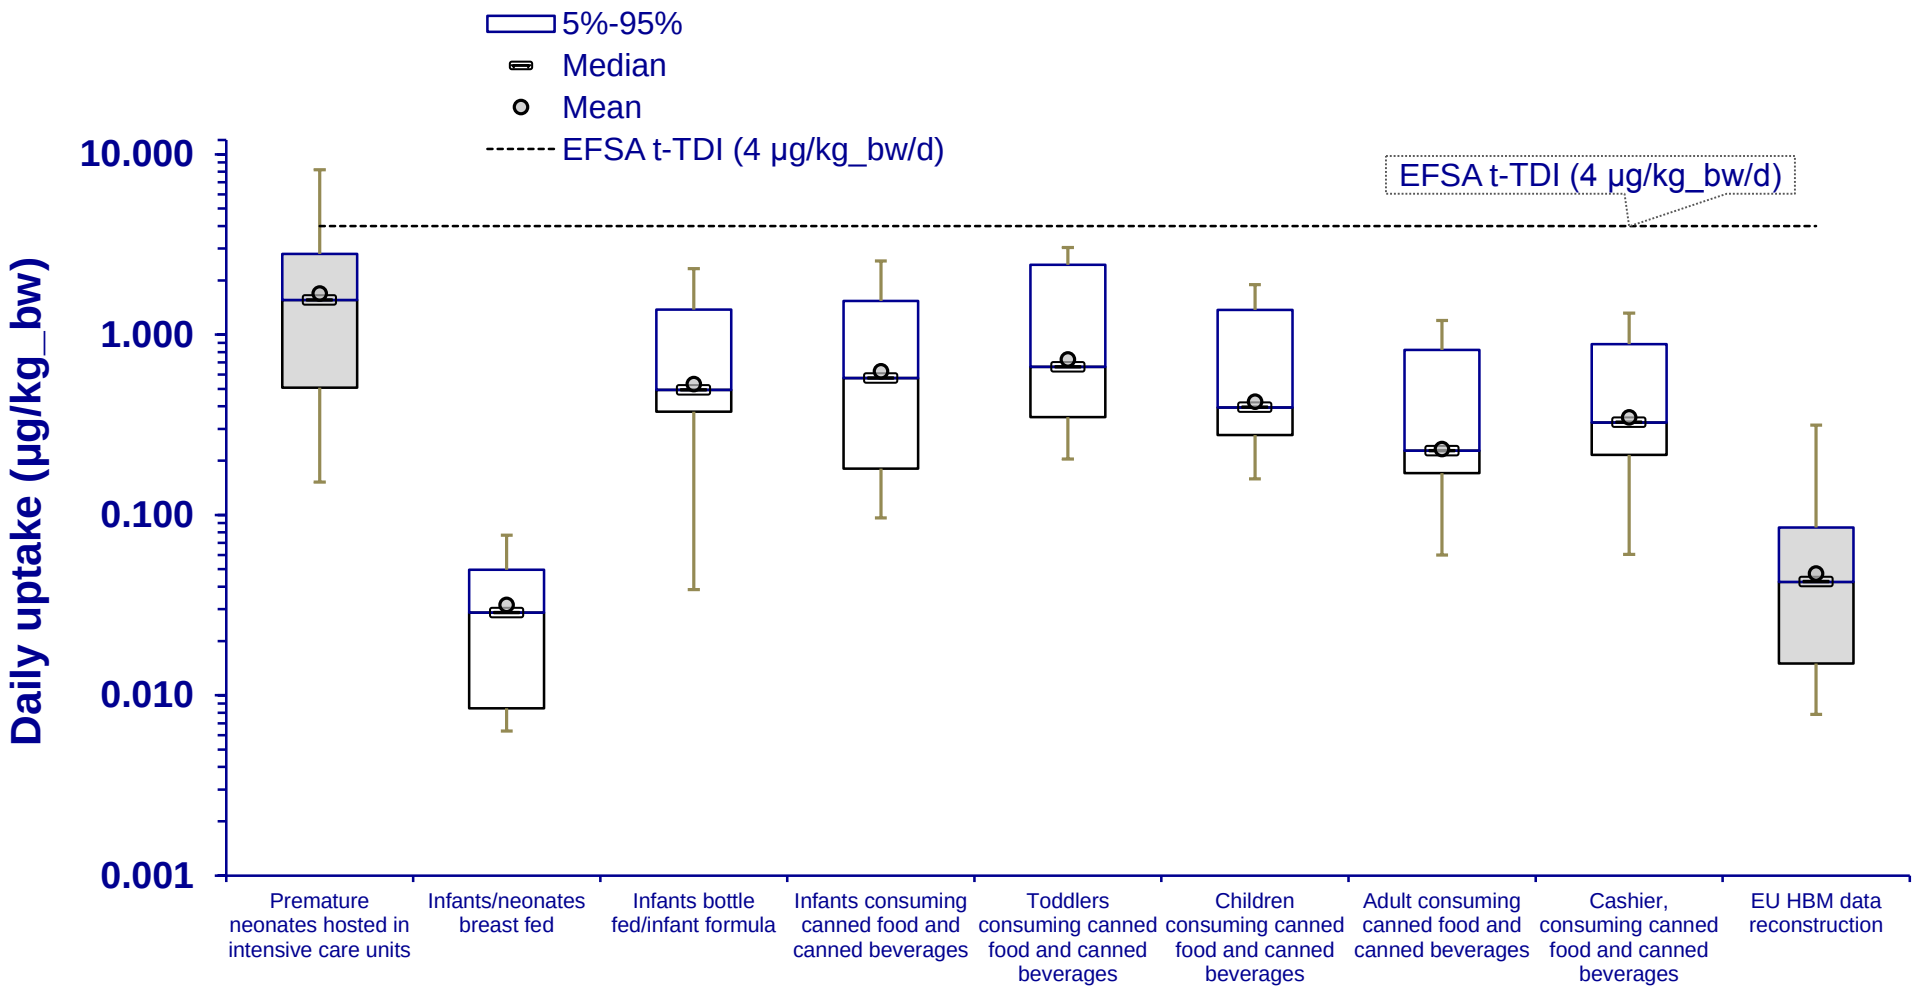
External exposure assessment



Internal dosimetry aspects of BPA toxicokinetics

- Wider inter-individual variability regarding glucuronidation capacity (significantly lower clearance for neonates/infants)
- Very strong plasma protein binding
- First-pass metabolism decisive for clearance – wide bioavailability differences are expected from routes beyond oral (up to six times higher internal dose concentrations for inhalation compared to oral)
- BPA-GLU de-conjugates to BPA in the stomach, increasing the actual dose during breast feeding, thus, the sum of BPA and BPA-GLU needs to be taken into account as BPA dose during breast feeding
- BPA-GLU de-conjugates to BPA in the placenta, increasing the actual dose during pregnancy

- The EFSA t-TDI of 4 μg/kg_bw/d was translated into internal exposure, found to correspond to a concentration of 0.013 μg/L of free plasma BPA (in adults).
- The use of internal dosimetry metrics allows the use of in vitro toxicological data for risk characterization. The ToxCast BPA *in vitro* assays provided six ER agonist or binding AC50 values for BPA, ranging from 0.6 to 1.7 μM. To calculate a conservative Biological Pathway Altering Dose (BPAD), the lowest ToxCast AC50 was selected, which is 0.64 μM for Attagene Factorial cis ERE assay.

Incorporating the uncertainty factors related to population response to xenobiotics, two different values are produced, namely the BPAD99, which is the permissible exposure level that accounts for population variability, and BPADL99, which is the permissible exposure level additionally accounting for uncertainty.

By using the reverse toxicokinetic approach that accounts for the concentration at steady state divided by the dose rate, the respective the estimated population parameters gives a BPAD99 of 0.44 μg/kg_bw/d, with lower one-sided confidence limit, BPADL99, of 0.16 mg/kg/day.

Using these external exposure values in our PBTK model, we derive equivalent internal dose of 1.44 and 0.52 μg/L respectively. These concentrations are almost 2 orders of magnitude higher than the BED derived from the EFSA t-TDI (0.013 μg/L).
